Introduction

Renal cell carcinoma (RCC) is one of the most common urinary tumors, causing over one hundred thousand deaths around the world annually [1,2]. With the develop of imaging technology, more and more renal tumors were found out in an early stage. However, the lack of obvious symptoms and signs still leads to metastatic disease in many patients when they were diagnosed. Targeted drugs, such as sunitinib, sorafenib and pazopanib, have significantly improved the prognosis of patients with metastatic renal cell carcinoma (mRCC) since 2006 [3-5]. With the surprising occurrence of immune checkpoint inhibitor, combined therapy has become the very first choice for mRCC patients [6,7]. However, in face of the malignant tumors, the effect of drug treatment is limited, so further explore of the develop mechanism of tumor is necessary.

CXC chemokine receptor type 4 (CXCR4) is an important molecule that highly expressed in a variety of cancers [8-10]. It was initially found to act as a co-receptor of T-tropic HIV viruses to entry CD4⁺ T cells [11]. CXCR4 binds to its ligand CXC motif chemokine ligand 12 (CXCL12), also known as Stromal cell-derived factor-1 (SDF-1), and then activate multiple pathways, such as PI3K/AKT pathway and Ras/Raf pathway, which lead to the enhance of diverse tumor biological behaviors, including proliferation, migration, invasion and transcriptional activation [12-14]. In our previous study,

Abstract

Renal cell carcinoma is a common malignant urinary tumor and CXCR4 plays an important role in the development of renal cell carcinoma. However, the role of c-Src gene in the development of renal cell carcinoma is still unclear. In this study, we found that CXCR4 can directly bind to SRC and CXCR4 is involved in the regulation of c-Src expression. C-Src is highly expressed in renal cell carcinoma and promotes cell division, proliferation, invasion and reduces apoptosis in renal cell carcinoma. Highly expressed c-Src is associated with poor prognosis in patients with RCC, and affects the infiltration of CD4⁺ T cells and macrophages in the tumor microenvironment. In addition, high SRC expression is associated with the expression of multiple immune checkpoints, high tumor mutation burden and high microsatellite instability which indicates the potential of SRC to predict the response to the immune checkpoint block therapy.

Keywords: CXCR4; SRC; Renal cell carcinoma

we found that non-muscle myosin heavy chain-IIA (NMMHC-IIA) and hypoxia-inducible factor-1 α (HIF-1 α) can interact with CXCR4 [15,16]. However, potential interacting proteins and concrete mechanisms need to be explored to help a more comprehensive understanding of the function of CXCR4.

The proto-oncogene c-Src is a member of Src family kinases (SFKs), a nine-gene family of non-receptor tyrosine kinases, consisting of SRC, YES, FYN, LCK, HCK, FGR, LYN, BLK and YRK [17-21]. As a cytoplasmic protein tyrosine kinase, SRC interacts with many focal-adhesion proteins, adaptor proteins and transcription factors in PI3K, MAPK, STAT3, FAK signaling pathways which contributes to its important role in modulation of cytoskeletal organization, angiogenesis, invasion, cell cycle progression and proliferation [17,22]. However, its function in the development of renal cell carcinoma remains to be explored.

In this study, the relationship between CXCR4 and c-Src and the role of c-Src in the development of renal cell carcinoma were explored.

Materials and Methods

Clinical RCC tissue samples

The study design was approved by the Changzheng Hospital Ethics Committee, and informed consent was obtained from each

patient. We obtained 29 pairs of tumor and adjacent tissue samples and 98 tumor tissue samples from patients with RCC underwent nephrectomy, partial or radical, at Changzheng Hospital, Naval Medical University, Shanghai, China.

Cell lines and culture conditions

Human RCC cell line (A498 and ACHN) was obtained from the Chinese Academy of Sciences (Shanghai, China) and underwent STR authentication. The cells were incubated in DMEM high glucose medium (Gibco) containing 10% fetal bovine serum (FBS) (Gibco) and 1% penicillin-streptomycin (Gibco). All cells were grown as a monolayer on the plastic cell culture dishes at 37°C in a humidified atmosphere containing 5% CO₂.

Lentiviral vectors and infection

The lentivirus encoding CXCR4, sh-CXCR4, sh-c-Src plasmids were packaged at GenePharma (Shanghai, China) and cells were infected following the manufacturer's instruction.

RNA isolation and RT-PCR

Total RNA was extracted from fresh-frozen tissues or cultured cells using RNAiso Plus (Takara) and then underwent reverse transcription (Takara, RR036A) on Veriti Dx platform (Applied Biosystems) and RT-PCR (Takara, RR420A) on StepOne platform (Applied Biosystems). Relative mRNA was analyzed using 2^{-ΔΔCT} method.

Western blotting

Total protein from fresh-frozen tissues or cultured cells was harvested with ice-cold Pierce IP (ThermoFisher) and protease inhibitor cocktail (Beyotime Biotechnology). Equivalent amounts of protein were separated on 10% SDS-PAGE (Epizyme Biotech), transblotted onto 0.22μm Amersham Protran NC membrane (Cytiva). Membranes were blocked with 5% skimmed milk in TBST buffer for 2 hours at 4°C and incubated with the indicated primary antibodies with gentle rocking overnight at 4°C. Membranes were further incubated with the corresponding HRP-conjugated secondary antibodies (Beyotime Biotechnology) for 2 hours at 4°C. Finally, protein bands were imaged using enhanced chemiluminescence detection kit (Epizyme Biotech) and analyzed with the chemiluminescence imager Chemi Doc XRS+ (BIO-RAD).

Coimmunoprecipitation

Co-IP was performed as the manufacturer's instructions (Pierce Co-Immunoprecipitation (Co-IP) Kit, ThermoFisher). Protein complex pull-down with CXCR4 antibody from total protein harvested from ACHN cells. The CXCR4-pull-down products were subjected to 10% denaturing polyacrylamide gel electrophoresis and visualized by silver staining. The protein bands were analyzed using MS/MS spectra and the results were re-confirmed by another co-immunoprecipitation using CXCR4 antibody and SRC antibody.

Immunohistochemistry

Paired tumor and adjacent paraffin tissue samples were cut into slices and conducted a common immunohistochemistry procedure with primary CXCR4 or SRC antibody (Proteintech) and appropriate secondary antibody.

Flow cytometry

The reagents used to detect cell cycle and apoptosis by flow

cytometry were purchased from BD Pharmingen and cells were tested according to the manufacturer's standard instructions.

Cell Counting Kit-8 (CCK-8) assay

Cells were seeded into 96-well culture plates (2x10³ cells per well). At indicated time, 10μl CCK-8 reagent (Dojindo Molecular Technologies) was added to each well and incubated for 2h at 37°C. Absorbance values at a wavelength of 450nm were recorded using a SpectraMax Paradigm microplate reader (Molecular Devices). Viability (%) was calculated based on the optical density (OD) values as follows: (OD of time sample - blank)/(OD of 0h control sample - blank) x 100%.

Transwell invasion assay

The transwell invasion assay were performed with the 8μm cell culture insert (BD Falcon) and Matrigel matrix (Corning) following the manufacturer's instructions. Cells were stained with 0.5% crystal violet.

Bioinformatics analysis

SRC expression in RCC was examined using the TIMER and UALCAN databases. The LinkedOmics database was used to study the signaling pathways related to SRC expression. Networks were generated using the STRING. TIMER and xCell were used to analyze the correlations among tumor-infiltrating immune cells. All analysis methods and R package were implemented by R foundation for statistical computing (2020) version 4.0.3 and software packages ggplot2 and pheatmap.

Statistical analysis

Statistical analysis was performed using the GraphPad Prism version 8.0 (GraphPad software, USA) and Statistical Package for Social Sciences (SPSS 17.0 for Windows, SPSS, Chicago, IL). The measurement data are presented as mean ± SD. An independent samples t test was used to analyze the differential expression levels of c-Src mRNA between the RCC tissues and the adjacent normal tissues from TCGA databases. Correlations between c-Src expression and clinicopathological characteristics were analyzed by the Pearson's Chi squared test. Overall survival (OS) analysis was performed by Kaplan-Meier plots and the differences were compared using the log-rank test. Univariate and multivariable analyses were performed using the Cox proportional hazards regression models. A two-tailed P value of 0.05 was considered statistically significant.

Results

SRC directly combine with CXCR4 and locates downstream CXCR4

In order to find potential proteins that interact with CXCR4, a co-immunoprecipitation (co-IP) was conducted using CXCR4 antibody and lysates of ACHN cells. The result showed the capacity of CXCR4 to bind to various proteins and the 60 kDa band was identified as c-Src (Figure 1A). A similar conclusion was reached by another two co-immunoprecipitation tests using SRC antibody to pull down protein complex in lysates of A498 cells and CXCR4 antibody to pull down protein complex in lysates of ACHN cells separately (Figure 1B). To clarify the relationship between CXCR4 and SRC, we detected the expression of CXCR4 and SRC in 29 pairs of tumor tissue and adjacent tissue using immunohistochemistry. The results showed

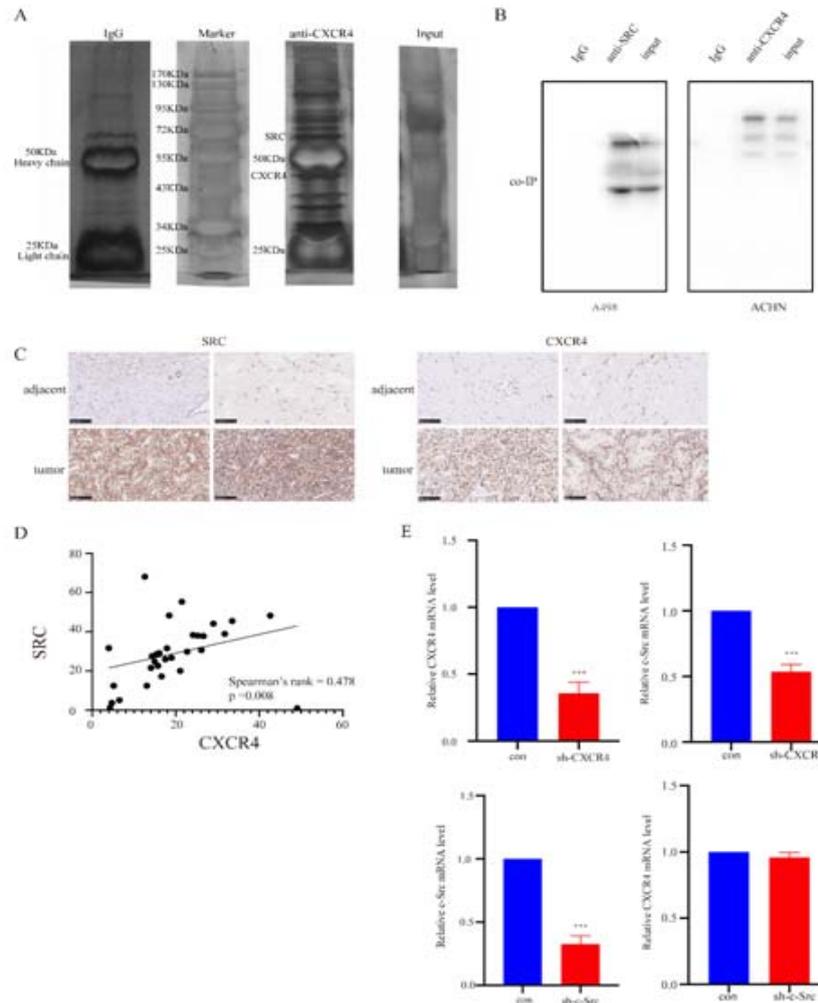

Figure 1: CXCR4 interacts with SRC and is involved in the regulation of c-Src. A) The co-IP result using CXCR4 antibody in ACHN cells. B) The co-IP results using SRC antibody in A498 cells and CXCR4 antibody in ACHN cells. C) The results of immunohistochemistry in paired RCC tumor and adjacent tissues. that both SRC and CXCR4 were highly expressed in RCC tissue (Figure 1C). Statistical analysis showed that the expression of SRC was positively correlated with the expression of CXCR4 (Figure 1D). Next, we considered whether c-Src locates upstream or downstream CXCR4. In order to clarify their relationship, we constructed A498 cell lines knocking-down CXCR4 and c-Src respectively, and detected the mRNA expression levels of the two genes by RT-PCR. It showed that the knockdown of CXCR4 significantly reduced the expression of c-Src and knockdown of c-Src did not affect the expression of CXCR4 on the contrary (Figure 1E). Therefore, we drew a conclusion that c-Src locates downstream CXCR4.

C-Src highly expressed in RCC and indicates poor prognosis

To clarify the role of c-Src in the development of renal cell carcinoma, we first checked the expression of c-Src in RCC tissues by Western-Blotting and RT-PCR. The results showed that c-Src is highly expressed in RCC tissues (Figure 2A and 2B). Patients with high c-Src expression had a poorer overall survival rate according to

our own follow-up data (Figure 2C). Bioinformatics analysis is used, and the results are just consistent with our conjectures. C-Src was highly expressed in the ccRCC cancer tissues compared with normal tissues (Figure 2D). Also, the expression of c-Src was higher in clinical late-stage and M1 stage tumors (Figure 2E and 2F), and high c-Src expression leads to a worse prognosis (Figure 3D).

CXCR4 is involved in the regulation to the functions of c-Src in RCC development

In order to clarify the role of high c-Src expression in the development of RCC and the regulatory role of CXCR4 on c-Src, c-Src knockdown, CXCR4 overexpression and simultaneously CXCR4 overexpression and c-Src knockdown A498 cell lines were constructed by lentivirus infection. The cell line constructions were verified by RT-PCR and Western Blotting (Figure 3A and 3B). Then flow cytometry test, CCK-8 assay and transwell invasion assay were progressed to check the influences on functions of RCC cell. The results showed that knockdown of c-Src significantly reduces cell division, cell proliferation and cell invasion and increases cell

apoptosis (Figure 3C-3F). By contrast, overexpression of CXCR4 can increase cell division, cell proliferation and cell invasion but reduce cell apoptosis (Figure 3C-3F). And overexpression of CXCR4 can rescue cells from the inhibition on cell division, cell proliferation and cell invasion and promotion on cell apoptosis causing by knockdown of c-Src (Figure 3C-3F).

SRC promote the development of RCC by affecting the tumor microenvironment

For a deeper sense of understanding on the function of c-Src in the development of RCC, we explored the interaction proteins of SRC by bioinformatics. The protein-protein interaction network (PPI network) displayed the top 45 proteins associated with SRC (Figure 4A). The GO and KEGG enrichment showed that those proteins join mainly in the ionic transportation and pH regulation (Figure 4B).

With the emergence of immune checkpoint block (ICB) therapy, the evaluation of tumor immune infiltration status in RCC patients gets more essential and may improve the treatment response rate. From the results of bioinformatics analysis, we found that SRC was correlated with low infiltration levels of macrophages ($p=1.68e-04$) and high infiltrating levels of CD4⁺ T cells ($p=4.04e-02$) (Figure 4C). Also, SRC was significantly correlated with high expression of immune checkpoints, such as CD274 ($p=1.08e-02$), CTLA4 ($p=1.39e-06$), TIGIT ($p=6.23e-05$), LAG3 ($p=6.24e-09$), and PDCD1 ($p=5.26e-09$) (Figure 4D). When analyzing the correlation between SRC expression and tumor mutation burden (TMB) and microsatellite instability (MSI), we found that SRC expression was positively correlated with TMB ($P=0.014$) and MSI ($P=0.002$) (Figure 4E and 4F), suggesting that c-Src may predict the clinical response to ICB in RCC patients.

Discussion

Because of the hidden onset and insensitivity to radiotherapy and chemotherapy, advanced RCC remains a common fatal malignant

tumor [23-25]. Although the emergence of targeted drugs improves the prognosis of patients with advanced renal cell carcinoma and the combination with immune checkpoint inhibitors further improves its efficacy, the overall benefit is still limited [3-7]. Therefore, it is still

necessary to study the development mechanism of RCC.

In our previous research, functions of CXCR4 in RCC development were studied. We found that CXCR4 nuclear localization

after binding to its ligand SDF-1 occurs in metastatic tissues but not the primary lesion [26]. Then, we found that CXCR4 knockdown inhibits cell growth and metastasis in RCC cells [27]. In order to learn more about the influence of the nuclear localization of CXCR4, we

first identified the nuclear localization sequence of CXCR4 in RCC by constructing expression plasmids of different deletants [28]. Then we found nuclear localization of CXCR4 is dependent on NMMHC-IIA in RCC [15]. Most importantly, we found that CXCR4 and hypoxia-inducible factor-1 α (HIF-1 α) colocalized in RCC cells and interacted with each other which formed a positive feed-forward loop to promote the development of RCC [16].

In this study, we found that CXCR4 can directly combine with SRC. This makes us wonder whether CXCR4 is involved in regulating the expression of c-Src. We found that CXCR4 knockdown significantly reduced the expression of c-Src but not vice versa. Therefore, we think c-Src may be a downstream molecule of CXCR4. The knockdown of c-Src significantly reduced cell division, cell proliferation and cell invasion and increased cell apoptosis. And overexpression of CXCR4 can rescue cells from the inhibition of cell division, cell proliferation and cell invasion and promotion of cell apoptosis causing by knockdown of c-Src. Thus, CXCR4 is involved in regulating the role of c-Src in promoting the development of RCC.

The results of bioinformatics analysis verified some of our conclusions and found that c-Src may play a role in regulating tumor microenvironment. We found that the expression level of c-Src affects the infiltration of immune cells in the tumor microenvironment and is related to the expression of multiple immune checkpoints which may indicate that c-Src can be a biomarker in screening patients suitable for immune checkpoint combined therapy.

Interaction between CXCR4 and c-Src was observed in many other cancers, such as breast cancer, prostate cancer and gastric cancer [29-32]. However, most of their studies only indirectly show that CXCR4 play a regulatory role to SRC. In our study, we found that SRC is one of the proteins directly bind to CXCR4 and is regulated by CXCR4 at both mRNA and protein levels in RCC. But the specific regulation mechanism of how CXCR4 influence the expression level of c-Src remains to be further studied to make clear how CXCR4 regulates the transcription of c-Src and what's the effect of direct binding on their own protein functions.

The phenomenon that Src expression was associated with immune cell infiltration was found in both benign and malignant diseases [20,33-35]. But the mechanism behind this phenomenon still needs further experimental proofs. There's a bioinformatics study showed that the differential expression of CXC kinase family affects the immune infiltration of RCC, and SRC family is the downstream target of CXC kinase family. This is consistent with our conclusion. However, the effects of SRC on the microsatellite instability score, tumor mutation burden score and the efficacy of immune checkpoint inhibitor therapy need to be further explored in clinical trials.

Overall, our study found that CXCR4 can directly bind to SRC and regulate the function of c-Src in RCC development. C-Src is involved in the regulation of immune infiltration in tumor microenvironment and affects tumor MSI and TMB score. It has the potential to be used as a screening marker of immune checkpoint inhibitors.
